Hi Prabhu,

I hope you're doing well.

As part of today's learning, I built a **User Validation Form** using React.js. The form collects PAN, Aadhaar, and GST details, and handles validation through controlled components and React hooks. After submission, the form transitions to a payment summary view, simulating a user onboarding experience.

This project helped me strengthen my understanding of:

1. React hooks (`**useState**`) for managing input fields

2. Controlled components and **form validation**

3. Conditional rendering and component navigation

4. Clean separation of logic and styling in component-based development

This helped me improve my skills in form handling, conditional rendering, and component structuring in React.

Moving forward, I plan to enhance this project by integrating it with **real-time APIs** for validating user credentials and dynamically fetching payment history, making the flow fully functional.

Best regards,

Yashwanth S
